Abstract

We analyze lepton flavour violating transitions, leptonic magnetic dipole moments (MDMs) and electric dipole moments (EDMs) in a class of models characterized by the flavour symmetry $A_4 \times Z_3 \times U(1)_{FN}$, whose choice is motivated by the approximate tri-bimaximal mixing observed in neutrino oscillations. We construct the relevant low-energy effective Lagrangian where these effects are dominated by dimension six operators, suppressed by the scale M of new physics. All the flavour breaking effects are universally described by the vacuum expectation values $\langle \Phi \rangle$ of a set of spurions. We separately analyze both a supersymmetric and a general case. While the observed discrepancy δa_μ in the anomalous MDM of the muon suggests M of order of a few TeV, several data require M above 10 TeV, in particular the limit on EDM of the electron. In the general case also the present limit on $BR(\mu \rightarrow e\gamma)$ requires $M > 10$ TeV, at least. The branching ratios for $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ are all expected to be of the same order. In the supersymmetric case the constraint from $\mu \rightarrow e\gamma$ is softened and it can be satisfied by a smaller scale M . In this case both the observed δa_μ and the current bound on $BR(\mu \rightarrow e\gamma)$ can be satisfied, at the price of a rather small value for $|\langle \Phi \rangle|$, of the order of a few percents, that reflects on a similar value for θ_{13} .

1 Introduction

Aim of this paper is to analyze the predictions of a class of models of lepton masses and mixing angles concerning processes which violate the individual lepton number, such as $\mu \rightarrow e\gamma$ and $\tau \rightarrow \mu\gamma$. We will focus on a flavour symmetry that contains the discrete group A_4 and is particularly successful in reproducing the lepton mixing angles observed in neutrino oscillations [1,2]. Such a mixing pattern is surprisingly close to the so-called tri-bimaximal (TB) one [3]. The experimental precision on the atmospheric and solar mixing angles has considerably improved in the last few years and now the solar mixing angle is known with a 1σ accuracy of about one and a half degrees. Since its first measurement the atmospheric mixing angle showed a steady tendency to be very close to maximal, and now its experimental error is of about four to five degrees. At present the TB scheme perfectly matches the data and it predicts a vanishing angle θ_{13} [4]:

$$\begin{aligned} \sin^2 \theta_{13} &< 0.032 & (\theta_{13} < 10.3^\circ) & (2\sigma) & \sin^2 \theta_{13}^{TB} &= 0 \\ \sin^2 \theta_{23} &= 0.45^{+0.16}_{-0.09} & (\theta_{23} = (42.1^{+9.2}_{-5.3})^\circ) & (2\sigma) & \sin^2 \theta_{23}^{TB} &= 1/2 \\ \sin^2 \theta_{12} &= 0.326^{+0.05}_{-0.04} & (\theta_{12} = (34.8^{+3.0}_{-2.5})^\circ) & (2\sigma) & \sin^2 \theta_{12}^{TB} &= 1/3 \end{aligned} \quad (1)$$

To a high degree of accuracy the TB mixing pattern can be derived by assuming that leptons transform as certain multiplets of the discrete flavour symmetry A_4 [5–10], realized at a very high energy scale Λ_f . The A_4 group is spontaneously broken at a scale $\langle\varphi\rangle \ll \Lambda_f$ by a set of scalar multiplets φ , the flavons, whose vacuum expectation values (VEVs) are subject to a special alignment. In models that have been explicitly constructed and analyzed, this alignment is not arranged by hand, but it is the natural consequence of the dynamics of the theory [6–10]. Moreover the TB mixing pattern is expected to be modified by corrections of order $\langle\varphi\rangle/\Lambda_f \ll 1$. When these corrections are accounted for, the mixing angle θ_{13} is no longer vanishing and becomes proportional to $\langle\varphi\rangle/\Lambda_f$. In these models the total lepton number is broken at a large scale Λ_L (possibly related to $\langle\varphi\rangle$) and light neutrinos are assumed to be of Majorana type. Depending on the specific way the total lepton number is violated (either by higher dimensional operators or via the see-saw mechanism), the neutrino mass spectrum can have different properties that can be tested in future experiments.

It would be highly desirable to reveal the characteristic A_4 symmetry pattern in other types of observables, not directly related to neutrino properties. Such a possibility becomes realistic if there is new physics at a much lower energy scale M , around $1 \div 10$ TeV. Indeed we have several indications, both from the experimental and from the theory side, that this can be the case. For instance, the observed discrepancy in the anomalous magnetic moment of the muon, the overwhelming evidence of dark matter, the evolution of the gauge coupling constants towards a common high-energy value and the solution of the hierarchy problem can all benefit from the existence of new particles around the TeV scale. In this paper we assume that such a new scale exists and that the associated degrees of freedom do not provide new sources of baryon and/or lepton number violation.

Therefore, at least four different scales are present in our approach: the lepton number breaking scale Λ_L , the scale of flavour breaking Λ_f , the scale introduced by the VEVs of the flavon fields $\langle\varphi\rangle$ and the new physics scale M . A generic hierarchy among the scales is

$M \ll \langle \varphi \rangle \ll \Lambda_f$ with Λ_L expected to be comparable to or smaller than Λ_f .

We will adopt an effective field theory approach, where the dominant physical effects of the new particles at low energies can be described by local dimension six operators, suppressed by two powers of the new mass scale M and explicitly conserving B and L . We can account for the flavour breaking effects by requiring invariance of these operators under the flavour symmetry and by encoding the symmetry breaking effects in the flavon fields. This approach is strictly related to, and indeed inspired by, that of minimal flavour violation (MFV) [11,12], where the flavour group G_f contains, in the lepton sector, $SU(3)_{ec} \times SU(3)_L$, and where the dimensionless symmetry breaking parameters are the Yukawa couplings themselves. While such a choice has the advantage that it can accommodate any pattern of lepton masses and mixing angles, it does not provide any clue about the origin of the approximate TB pattern observed in the lepton mixing matrix U_{PMNS} . For this reason, here we choose a flavour group that includes the discrete factor A_4 : $G_f = A_4 \times Z_3 \times U(1)_{FN}$, a sort of minimal choice to properly account for both, the neutrino and the charged lepton mass spectra. Once the choice of the group has been made, we will explicitly build the operators of dimension six in the lepton sector. They will contribute to physical effects like the anomalous magnetic moments (MDMs) of the charged leptons, their electric dipole moments (EDMs) and lepton flavour violating (LFV) transitions like $\mu \rightarrow e\gamma$ and $\tau \rightarrow \mu\gamma$ ¹. We will separately treat the general case where no further requirement is enforced and the supersymmetric case, where additional constraints are present.

Among the observable quantities that we have analyzed, only the anomalous MDM of the muon suggests a relatively small scale M , of the order of few TeV. Apart from this indication, in the non-supersymmetric case there are several data that require M above 10 TeV. First of all the EDM of the electron that represents the strongest bound: $M > 80$ TeV. The limits on the τ decays $\tau^- \rightarrow \mu^+ e^- e^-$ and $\tau^- \rightarrow e^+ \mu^- \mu^-$ push the scale M above approximately 15 TeV. Finally, to satisfy the present limit on $BR(\mu \rightarrow e\gamma)$, we need $M > 10$ TeV, at least. We also find that the branching ratios for $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ are all of the same order. Given the present limit on $BR(\mu \rightarrow e\gamma)$, this implies that $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ have rates much smaller than the present (and near future) sensitivity. In the supersymmetric case the bound from $\mu \rightarrow e\gamma$ is softened, due to a cancellation occurring in the relevant dipole operator. Depending on $|\langle \varphi \rangle / \Lambda_f|$, whose typical value lies in the range $0.001 \div 0.05$, M can be as small as $0.7 \div 14$ TeV. Therefore in a portion of the parameter space our model can simultaneously fit the observed discrepancy of the anomalous MDM of the muon and respect the current bound on $BR(\mu \rightarrow e\gamma)$. The allowed values for $\langle \varphi \rangle / \Lambda_f$ are rather small, of the order of a few percents at most and this represents also the expected range of θ_{13} . To tolerate such a low scale M , additional mechanisms are required to suppress at least the electron EDM and the rates for $\tau^- \rightarrow \mu^+ e^- e^-$ and $\tau^- \rightarrow e^+ \mu^- \mu^-$.

The paper is organized as follows: in the second section we give a more extended overview of this approach, without specifying the flavour symmetry and its breaking pattern. Then we move to the class of models we are interested in. We will characterize them

¹For a discussion on LFV without a specific flavour symmetry, see for instance [13–16]. For a recent review on the subject see ref. [17].

in section 3. We will display the corresponding low-energy effective Lagrangian in section 4. Subsequently we will derive the predictions for leptonic MDMs, EDMs and LFV transitions both without (section 5) and with (section 6) the additional constraints implied by supersymmetry. These sections contain the main results of our paper. They are compared to those of MFV in section 7 and summarized in section 8. More technical aspects are discussed in appendix A and B.

2 Low-energy effective Lagrangian for lepton flavour violation

We consider the possibility that the pattern of lepton masses and mixing angles that emerged in the last years with the discovery of neutrino oscillations is dictated by some flavour symmetry, realized at a very high energy scale Λ_f [18]. So far all the attempts to build a theory of fermion masses based on a flavour symmetry indicate that such a symmetry cannot be exact and that the main features of the fermion spectrum are reproduced by specific symmetry breaking patterns. In particular, the closeness of the observed lepton mixing to the TB mixing pattern is successfully reproduced in models with spontaneously broken flavour symmetries and special vacuum alignment properties. Here we assume that the flavour group G_f , which will be specified later on, is spontaneously broken by a set of adimensional small parameters $\langle\Phi\rangle$, $|\langle\Phi\rangle| \ll 1$. These should be interpreted as ratios between VEVs of flavon scalar fields φ , transforming non-trivially under G_f , and some fundamental scale Λ_f , above which an ultraviolet completion of the theory describes the details of the flavour dynamics. The consistency of this picture requires that $|\langle\varphi\rangle| \ll \Lambda_f$. We also assume that the total lepton number (or better, the combination $B-L$) is violated at a large scale Λ_L , so that the light neutrinos get their masses through the low-energy operator [19]:

$$\mathcal{L}_\nu = \frac{1}{\Lambda_L} (\tilde{H}^\dagger l)^T Y (\tilde{H}^\dagger l) + h.c. \quad (2)$$

where l denotes the three lepton doublets of the standard model (SM) and H is the Higgs scalar doublet². In this scenario, the Yukawa couplings y_f ($f = l, u, d$) of the SM and the matrix Y in $\mathcal{L}_\nu$ become functions of $\langle\Phi\rangle$:

$$y_f = y_f(\langle\Phi\rangle) \quad , \quad Y = Y(\langle\Phi\rangle) \quad , \quad (3)$$

so that, by treating $\langle\Phi\rangle$ as spurions transforming under G_f as the corresponding parent scalar fields, the whole theory is formally invariant under G_f . Under the assumption that

²We adopt two-component spinor notation, so for example e ($\bar{e}^c$) denotes the left-handed (right-handed) component of the electron field. For instance, in terms of the four-component spinor $\psi_e^T = (e \ \bar{e}^c)$, the bilinears $\bar{e}\bar{\sigma}^\nu e$ and $e^c\sigma^\nu\bar{e}^c$ correspond to $\bar{\psi}_e\gamma^\nu P_L\psi_e$ and $\bar{\psi}_e\gamma^\nu P_R\psi_e$ [$P_{L,R} = \frac{1}{2}(1\mp\gamma^5)$] respectively. We take $\sigma^\mu \equiv (1, \vec{\sigma})$, $\bar{\sigma}^\mu \equiv (1, -\vec{\sigma})$, $\sigma^{\mu\nu} \equiv \frac{1}{4}(\sigma^\mu\bar{\sigma}^\nu - \sigma^\nu\bar{\sigma}^\mu)$, $\bar{\sigma}^{\mu\nu} \equiv \frac{1}{4}(\bar{\sigma}^\mu\sigma^\nu - \bar{\sigma}^\nu\sigma^\mu)$ and $g_{\mu\nu} = \text{diag}(+1, -1, -1, -1)$, where $\vec{\sigma} = (\sigma^1, \sigma^2, \sigma^3)$ are the 2×2 Pauli matrices. Here the four-component matrix γ^μ is in the chiral basis, where the 2×2 blocks along the diagonal vanish, the upper-right block is given by σ^μ and the lower-left block is equal to $\bar{\sigma}^\mu$.

$|\langle\Phi\rangle| \ll 1$, the functions y_f and Y can be expanded in powers of $\langle\Phi\rangle$ and only a limited number of terms gives a non-negligible contribution ³.

Even when G_f and $\langle\Phi\rangle$ are completely specified, as in the case we are going to consider in this paper, if Λ_L and Λ_f are much larger than the electroweak scale, we are left with a limited number of tests of the above picture. Of course, there are still several parameters that remain to be measured or constrained: neutrinoless double beta decay, the mixing angle θ_{13} , the type of neutrino mass ordering, the absolute neutrino mass scale and the CP-violating phases. However it would be highly desirable to find evidence of the flavour symmetry in other types of processes. Such a possibility opens up if there is new physics at a much closer energy scale M , around $1 \div 10$ TeV. Here we assume that such a new scale exists and that the associated degrees of freedom do not provide new sources of baryon and/or lepton number violation ⁴.

Therefore, in the language of effective field theories, the dominant physical effects of the new particles at low energies can be described by dimension six operators, suppressed by two powers of the new mass scale M and explicitly conserving B and L . If we focus on the lepton sector only, the leading terms of the relevant effective Lagrangian are:

$$\mathcal{L}_{eff} = \mathcal{L}_{KT} + e^{cT} H^\dagger y_l l + \mathcal{L}_\nu + i \frac{e}{M^2} e^{cT} H^\dagger \sigma^{\mu\nu} F_{\mu\nu} \mathcal{M} l + h.c. + [4\text{-fermion operators}] \quad (4)$$

where $\mathcal{L}_{KT}$ stands for the kinetic terms, e is the electric charge and e^c the set of SU(2) lepton singlets. The complex three by three matrix $\mathcal{M}$, with indices in the flavour space, is a function of $\langle\Phi\rangle$:

$$\mathcal{M} = \mathcal{M}(\langle\Phi\rangle) \quad (5)$$

Invariance under $SU(2) \times U(1)$ gauge transformations is guaranteed if $F_{\mu\nu}$ is any arbitrary combination of $B_{\mu\nu}$, the field strength of U(1), and $\sigma^a W_{\mu\nu}^a$, the non-Abelian field strength of SU(2). Here we are interested in the component of this combination along the direction of the unbroken $U(1)_{em}$ and we identify $F_{\mu\nu}$ with the electromagnetic field strength. We can imagine that we derive such an effective Lagrangian from a fundamental theory by integrating out two different sets of modes. In a first step we can integrate out the flavon fields and the possible degrees of freedom associated with the violation of $B - L$, thus obtaining a complete set of mass terms for all the light particles including neutrinos, charged fermions and the quanta with masses around the TeV scale. Subsequently, around the scale $M = 1 \div 10$ TeV, we integrate out these additional quanta and we generate the other operators listed in eq. (4). The latter are still invariant under G_f , once we treat the symmetry breaking parameters as spurions.

In this way we can capture all flavour symmetry breaking effects and keep a high degree of predictability since the expansion in the small symmetry breaking parameters can be

³An exception occurs when the dimension five operator $\mathcal{L}_\nu$ arises from the see-saw mechanism. For instance, if right-handed neutrinos are present, there can be renormalizable interactions between them and the flavons. By integrating out the right-handed neutrinos, we find that Λ_L itself is proportional to the mass scale associated with $\langle\varphi\rangle$. In this case the dimension five operator contains a simple pole in $\langle\Phi\rangle$ and is no longer local in the symmetry breaking parameters. For operators violating the lepton number L we will allow for a generalized power expansion containing poles in $\langle\Phi\rangle$.

⁴In our convention, the masses of the new particles are of order $gM/4\pi$, if the underlying theory is weakly interacting with a typical coupling constant g .

truncated after few terms⁵. Thereby, the same symmetry breaking parameters that control lepton masses and mixing angles also control the flavour pattern of the other operators in $\mathcal{L}_{eff}$. Moreover the effects described by these operators are suppressed by $1/M^2$ and not by inverse powers of the larger scales Λ_f and Λ_L and this opens up the possibility that they might be observable in the future.

In a field basis where the kinetic terms are canonical and the charged lepton mass matrix is diagonal, where we will denote vectors and matrices with a hat, the real and imaginary parts of the matrix elements $\hat{\mathcal{M}}_{ii}$ are proportional to the MDMs a_i and to the EDMs d_i of charged leptons, respectively [12, 16, 17, 21]:

$$a_i = 2m_i \frac{v}{\sqrt{2}M^2} \text{Re}\hat{\mathcal{M}}_{ii} \quad , \quad d_i = e \frac{v}{\sqrt{2}M^2} \text{Im}\hat{\mathcal{M}}_{ii} \quad (i = e, \mu, \tau) \quad , \quad (6)$$

where $v \approx 246$ GeV is the electroweak breaking scale, defined as $\sqrt{2}$ times the VEV of the real, electrically neutral, component of H . The off-diagonal elements $\hat{\mathcal{M}}_{ij}$ describe the amplitudes for the LFV transitions $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ [12, 13, 16, 17, 21–23]:

$$\frac{BR(l_i \rightarrow l_j \gamma)}{BR(l_i \rightarrow l_j \nu_i \bar{\nu}_j)} = \frac{12\sqrt{2}\pi^3\alpha}{G_F^3 m_i^2 M^4} \left(|\hat{\mathcal{M}}_{ij}|^2 + |\hat{\mathcal{M}}_{ji}|^2 \right) \quad (7)$$

where α is the fine structure constant, G_F is the Fermi constant and m_i is the mass of the lepton l_i . Finally the four-fermion operators describe other flavour violating processes like $\tau^- \rightarrow \mu^+ e^- e^-$ and $\tau^- \rightarrow e^+ \mu^- \mu^-$. In this paper our focus will be mainly on the processes $\mu \rightarrow e\gamma$ and $\tau \rightarrow \mu\gamma$ and we will make only some comments on the four-fermion operators.

3 Models with A_4 flavour symmetry

So far the discussion has been rather general and applies to any theory with a spontaneously broken flavour symmetry. Several models have been proposed to produce the TB mixing scheme [5–10, 24] and among the most economic and simplest ones are those based on the discrete group A_4 [5–10]. A_4 is the group of even permutations of four objects, isomorphic to the group of discrete rotations in the three-dimensional space that leave invariant a regular tetrahedron. It is generated by two elements S and T obeying the relations [25]:

$$S^2 = (ST)^3 = T^3 = 1 \quad . \quad (8)$$

It has three independent one-dimensional representations, 1, 1' and 1'' and one three-dimensional representation 3. We present a set of generators S and T for the various representations, and the relevant multiplication rules in appendix A. The group A_4 has two obvious subgroups: G_S , which is a reflection subgroup generated by S , and G_T , which is

⁵A non-analytic dependence on the symmetry breaking parameters $\langle\Phi\rangle$ can be induced by renormalization group running from the high energy scale $\langle\varphi\rangle$ down to energies below the electroweak scale. Such a dependence can only be determined when all the degrees of freedom lighter than $\langle\varphi\rangle$ are known. In MFV similar effects have been studied in ref. [20].

the group generated by T , isomorphic to Z_3 . These subgroups are of interest for us because G_S and G_T are the relevant low-energy symmetries of the neutrino and the charged-lepton sectors at leading order, respectively. The TB mixing is then a direct consequence of this special symmetry breaking pattern, which is achieved via the vacuum misalignment of triplet scalar fields. If $\varphi = (\varphi_1, \varphi_2, \varphi_3)$ denotes the generic scalar triplet, the VEV

$$\langle \varphi \rangle \propto (1, 1, 1) \quad (9)$$

breaks A_4 down to G_S , while

$$\langle \varphi \rangle \propto (1, 0, 0) \quad (10)$$

breaks A_4 down to G_T .

Concerning the flavour group G_f , following ref. [6–8] we will choose

$$G_f = A_4 \times Z_3 \times U(1)_{FN} \quad (11)$$

The three factors in G_f play different roles. The spontaneous breaking of the first one, A_4 , is directly responsible for the TB mixing. The Z_3 factor is a discrete version of the total lepton number and is needed in order to avoid large mixing effects between the flavons that give masses to the charged leptons and those giving masses to neutrinos. Finally, $U(1)_{FN}$ is responsible for the hierarchy among charged fermion masses [26]. The flavour symmetry breaking sector of the model includes the scalar fields φ_T , φ_S , ξ and θ . The transformation properties of the lepton fields l , e^c , μ^c , τ^c , of the electroweak scalar doublet H and of the flavon fields are summarized in table 1. We also assume the following pattern of VEVs for the flavon fields:

$$\begin{aligned} \frac{\langle \varphi_T \rangle}{\Lambda_f} &= (u, 0, 0) + (c_1 u^2, c_2 u^2, c_3 u^2) + O(u^3) \\ \frac{\langle \varphi_S \rangle}{\Lambda_f} &= c_b (u, u, u) + O(u^2) \\ \frac{\langle \xi \rangle}{\Lambda_f} &= c_a u + O(u^2) \\ \frac{\langle \theta \rangle}{\Lambda_f} &= t \end{aligned} \quad (12)$$

where $c_{1,2,3,a,b}$ are numbers of order one, while u and t are the small symmetry breaking parameters of the theory. All these quantities are in general complex. Notice that we have explicitly displayed the sub-leading $O(u^2)$ corrections only for the field φ_T . Those for the fields φ_S and ξ are not needed in the present analysis: they have no special pattern and are relevant when discussing corrections to neutrino masses and mixing angles. It has been shown in ref. [7] how it is possible to achieve this pattern in a natural way, as the result of the minimization of the scalar potential of the theory. In that case the model was supersymmetric, but an analogous pattern can also be obtained in other, non-supersymmetric, versions. Note that in the supersymmetric case the $O(u^2)$ corrections to φ_T obey $c_2 = c_3$.

The flavour group of eq. (11) and the set of flavon fields and their VEVs of eq. (12) can be used to obtain neutrino masses with an approximate TB mixing, both in the presence

Field	l	e^c	μ^c	τ^c	H	φ_T	φ_S	ξ	θ
A_4	3	1	$1''$	$1'$	1	3	3	1	1
Z_3	ω	ω^2	ω^2	ω^2	1	1	ω	ω	1
$U(1)_{FN}$	0	2	1	0	0	0	0	0	-1

Table 1: The transformation rules of the fields under the symmetries associated with the groups A_4 , Z_3 and $U(1)_{FN}$.

of right-handed neutrinos from the see-saw mechanism and directly from a set of higher dimensional operators [7] (with the only difference that, in the first case, the flavons φ_S and ξ transform with ω^2 under Z_3). Therefore the effective Lagrangian, (4), and the discussion of the related LFV processes, is exactly the same in both cases, at variance with MFV where the flavour group in the see-saw case becomes larger [12].

Before going into the details of the model, we recall that at the leading order the Yukawa couplings in eq. (3) are given by:

$$y_l = \begin{pmatrix} \hat{y}_e t^2 & 0 & 0 \\ 0 & \hat{y}_\mu t & 0 \\ 0 & 0 & \hat{y}_\tau \end{pmatrix} u \quad , \quad (13)$$

$$Y = \begin{pmatrix} a + 2b/3 & -b/3 & -b/3 \\ -b/3 & 2b/3 & a - b/3 \\ -b/3 & a - b/3 & 2b/3 \end{pmatrix} u \quad , \quad (14)$$

where $\hat{y}_e$, $\hat{y}_\mu$, $\hat{y}_\tau$, a and b are numbers of order one. At this order the mass matrix for the charged leptons is diagonal with the relative hierarchy described by the parameter t . We will take

$$|t| \approx 0.05 \quad . \quad (15)$$

In the same approximation, the neutrino mass matrix is diagonalized by the transformation:

$$U_{TB}^T m_\nu U_{TB} = \frac{v^2}{\Lambda_L} \text{diag}(a + b, a, -a + b) u \quad , \quad (16)$$

where U_{TB} , up to phases, is the unitary matrix of the TB mixing [3]:

$$U_{TB} = \begin{pmatrix} \sqrt{2/3} & 1/\sqrt{3} & 0 \\ -1/\sqrt{6} & 1/\sqrt{3} & -1/\sqrt{2} \\ -1/\sqrt{6} & 1/\sqrt{3} & +1/\sqrt{2} \end{pmatrix} \quad . \quad (17)$$

The symmetry breaking parameter u should lie in the range

$$0.001 < |u| < 0.05 \quad , \quad (18)$$

the lower bound coming from the requirement that the Yukawa coupling of the τ does not exceed 4π , and the upper bound coming from the requirement that the higher order

corrections, so far neglected, do not modify too much the leading TB mixing. Indeed, the inclusion of higher order corrections modifies all mixing angles by quantities of relative order u , especially we should keep the agreement between the predicted and measured value of the solar angle within few degrees. The unknown angle θ_{13} is expected to be of order $|u|$. Notice that, in most of the allowed range, we have $|u| < |t|$. Such a framework can also be extended to the quark sector [9, 27].

4 Low-energy effective Lagrangian with A_4 flavour symmetry

To evaluate the matrix of dipole moments $\mathcal{M}$ we should analyze the Lagrangian of the model:

$$\mathcal{L}_{eff} = \mathcal{L}_{KT} + \mathcal{L}_Y + \mathcal{L}_{dip} + \dots \quad (19)$$

Each of the terms on the right-hand side can be thought of as an expansion in powers of the flavon fields. Since we have two independent symmetry breaking parameters, u and t , see eqs. (12), we consider a double expansion of $\mathcal{L}_{eff}$ in powers of u and t . In this expansion we keep terms up to the second order in u , i.e. terms quadratic in the fields $\varphi_{S,T}$ and ξ . The expansion in the parameter t , responsible for the breaking of the Froggatt-Nielsen $U(1)_{FN}$ symmetry, will be stopped at the first non-trivial order, that is by allowing as many powers of the θ field as needed in order to obtain non-vanishing values for all the entries of the matrices describing lepton masses and dipole moments ⁶. Finally, second order corrections in u also arise from the sub-leading terms of the VEV $\langle \varphi_T \rangle$, eq. (12), and will be included in our estimates.

4.1 Kinetic terms

The expansion of the kinetic terms can be written as:

$$\mathcal{L}_{KT} = \mathcal{L}_{KT}^{(0)} + \mathcal{L}_{KT}^{(1)} + \mathcal{L}_{KT}^{(2)} + \dots \quad (20)$$

The leading order term is given by

$$\mathcal{L}_{KT}^{(0)} = ik_0 \sum_{i=1}^3 \bar{l}_i \bar{\sigma}^\mu D_\mu l_i + i \sum_{i=1}^3 (k_0^c)_i \bar{l}_i^c \bar{\sigma}^\mu D_\mu l_i^c \quad (21)$$

where the quantities k_0 and $(k_0^c)_i$ can be further expanded in powers of the field θ :

$$k_0 = 1 + \hat{k} \frac{|\theta|^2}{\Lambda_f^2} + \dots, \quad (k_0^c)_i = 1 + \hat{k}_i^c \frac{|\theta|^2}{\Lambda_f^2} + \dots \quad (22)$$

⁶Concerning the kinetic terms we observe that we can additionally write down operators involving the total invariant $\theta^\dagger \theta = |\theta|^2$. These contribute to the diagonal elements of the kinetic terms. In the kinetic terms of the left-handed fields they can be safely neglected, since the leading order correction is of $O(u)$. For the kinetic terms of the right-handed fields, they contribute at the same order as the terms arising through a double flavon insertion.

Note that for our purposes it is enough to expand k_0 up to the zeroth order and $(k_0^c)_i$ up to the second order in t . At the first order in u we have only one type of operator contributing to the kinetic terms

$$\mathcal{L}_{KT}^{(1)} = i \frac{k}{\Lambda_f} (\varphi_T \bar{l} \bar{\sigma}^\mu D_\mu l) + h.c. \quad (23)$$

where k is a coefficient of order one. Here and in what follows, by a parenthesis $(\dots)$ we denote an invariant under A_4 , $(\dots)'$ denotes the $1'$ singlet and so on. At the second order in u we have a richer structure:

$$\mathcal{L}_{KT}^{(2)} = \mathcal{L}_{KTL}^{(2)} + \mathcal{L}_{KTR}^{(2)} \quad , \quad (24)$$

with the labels L and R referring to lepton doublets l and singlets e^c, μ^c, τ^c , respectively. For lepton doublets we find:

$$\mathcal{L}_{KTL}^{(2)} = i \sum_{i=1}^7 \frac{k_i}{\Lambda_f^2} (X_i \bar{l} \bar{\sigma}^\mu D_\mu l) \quad (25)$$

where X is the list of Z_3 -invariant operators, bilinear in the flavon fields $\varphi_{S,T}$ and ξ ,

$$X = \left\{ \xi^\dagger \xi, \varphi_T^2, (\varphi_T^\dagger)^2, \varphi_T^\dagger \varphi_T, \varphi_S^\dagger \varphi_S, \xi^\dagger \varphi_S, \varphi_S^\dagger \xi \right\} \quad , \quad (26)$$

and there are obvious relations among the coefficients k_i in order to assure hermiticity. Note that the sum in eq. (25) runs over all bilinears which can couple to form A_4 -invariants. Whether they lead to a non-trivial contribution to the sum depends on the VEVs of the flavons. For lepton singlets, we can distinguish a diagonal contribution and a non-diagonal one:

$$\mathcal{L}_{KTR}^{(2)} = [\mathcal{L}_{KTR}^{(2)}]_d + [\mathcal{L}_{KTR}^{(2)}]_{nd} \quad (27)$$

$$[\mathcal{L}_{KTR}^{(2)}]_d = i \frac{1}{\Lambda_f^2} \sum_{i=1}^5 \left[(k_e^c)_i (X_i) \bar{e}^c \bar{\sigma}^\mu D_\mu e^c + (k_\mu^c)_i (X_i) \bar{\mu}^c \bar{\sigma}^\mu D_\mu \mu^c + (k_\tau^c)_i (X_i) \bar{\tau}^c \bar{\sigma}^\mu D_\mu \tau^c \right] \quad (28)$$

$$\begin{aligned} [\mathcal{L}_{KTR}^{(2)}]_{nd} &= i \sum_{i=2}^5 \left[\frac{(k_{e\mu}^c)_i}{\Lambda_f^3} (X_i)' \theta^\dagger \bar{e}^c \bar{\sigma}^\mu D_\mu \mu^c + h.c. \right] \\ &+ i \sum_{i=2}^5 \left[\frac{(k_{e\tau}^c)_i}{\Lambda_f^4} (X_i)'' (\theta^\dagger)^2 \bar{e}^c \bar{\sigma}^\mu D_\mu \tau^c + h.c. \right] \\ &+ i \sum_{i=2}^5 \left[\frac{(k_{\mu\tau}^c)_i}{\Lambda_f^3} (X_i)' \theta^\dagger \bar{\mu}^c \bar{\sigma}^\mu D_\mu \tau^c + h.c. \right] \end{aligned} \quad (29)$$

Due to the structure of the flavon VEVs only the term with $i = 5$ gives a non-vanishing contribution in the sum in eq. (29). When the flavon fields acquire a VEV according to the pattern assumed in eq. (12), the term $\mathcal{L}_{KT}$ gives rise to non-canonical kinetic terms for the lepton fields, of the following form:

$$\mathcal{L}_{KT} = i K_{ij} \bar{l}_i \bar{\sigma}^\mu D_\mu l_j + i K_{ij}^c \bar{l}_i^c \bar{\sigma}^\mu D_\mu l_j^c \quad (30)$$

$$K = \begin{pmatrix} 1 + O(u) & O(u^2) & O(u^2) \\ O(u^2) & 1 + O(u) & O(u^2) \\ O(u^2) & O(u^2) & 1 + O(u) \end{pmatrix} \quad (31)$$

$$K^c = \begin{pmatrix} 1 + O(u^2, t^2) & O(u^2 t) & O(u^2 t^2) \\ O(u^2 t) & 1 + O(u^2, t^2) & O(u^2 t) \\ O(u^2 t^2) & O(u^2 t) & 1 + O(u^2, t^2) \end{pmatrix} \quad (32)$$

As one can see, the corrections to the kinetic terms which render these non-canonical are small (at most at order $O(u)$ and $O(t^2)$). They have to be taken into account when calculating the lepton masses and the dipole transitions induced by the matrix $\hat{\mathcal{M}}$. However, an explicit calculation shows that at the leading order in our expansion parameters the charged lepton masses and the elements of $\hat{\mathcal{M}}$ are not affected by these non-canonical kinetic terms [28]. For this reason we have omitted in K and K^c the order one parameters that multiply the powers of t and u .

4.2 Lepton mass terms

We now move to the operators that give rise to the Yukawa couplings:

$$\mathcal{L}_Y = \mathcal{L}_l + \mathcal{L}_\nu \quad (33)$$

There is a part responsible for the charged lepton masses

$$\mathcal{L}_l = \mathcal{L}_l^{(1)} + \mathcal{L}_l^{(2)} + \dots \quad (34)$$

$$\begin{aligned} \mathcal{L}_l^{(1)} &= \frac{y_e}{\Lambda_f^3} \theta^2 e^c H^\dagger (\varphi_T l) + \frac{y_\mu}{\Lambda_f^2} \theta \mu^c H^\dagger (\varphi_T l)' + \frac{y_\tau}{\Lambda_f} \tau^c H^\dagger (\varphi_T l)'' \\ &+ \frac{y_e'}{\Lambda_f^3} \theta^2 e^c H^\dagger (\varphi_T^\dagger l) + \frac{y_\mu'}{\Lambda_f^2} \theta \mu^c H^\dagger (\varphi_T^\dagger l)' + \frac{y_\tau'}{\Lambda_f} \tau^c H^\dagger (\varphi_T^\dagger l)'' + h.c. \end{aligned} \quad (35)$$

The terms of eqs. (35) give rise to y_l as shown in eq. (13), if we define

$$u = |u| e^{i\psi} \quad , \quad \hat{y}_f = y_f + y_f' e^{-2i\psi} \quad (f = e, \mu, \tau) \quad . \quad (36)$$

At the next order in u we find:

$$\mathcal{L}_l^{(2)} = \sum_{i=2}^7 \frac{y_e^i}{\Lambda_f^4} \theta^2 e^c H^\dagger (X_i l) + \sum_{i=2}^7 \frac{y_\mu^i}{\Lambda_f^3} \theta \mu^c H^\dagger (X_i l)' + \sum_{i=2}^7 \frac{y_\tau^i}{\Lambda_f^2} \tau^c H^\dagger (X_i l)'' + h.c. \quad (37)$$

where the coefficients y_e^i , y_μ^i and y_τ^i are numbers of order one ⁷. Note that due to the special vacuum structure, eq. (12), the term with $i = 5$ in the sum in eq. (37) gives a

⁷Due to assumed pattern of VEVs, eq. (12), each bilinear X_i gives rise to a single contribution to the lepton masses: out of the several possible ways of combining X_i with l to form the desired A_4 singlet, only one has a non-vanishing VEV, at order u^2 . Thus there is no ambiguity in the parameters y_f^i , when discussing the lepton mass matrix.

vanishing contribution. From eqs. (35) and (37), after the breaking of the flavour and the electroweak symmetries, we find the following matrix of Yukawa couplings for the charged leptons:

$$y_l = \begin{pmatrix} \hat{y}_e t^2 u + z_e^{(1)} t^2 u^2 & z_e^{(2)} t^2 u^2 & z_e^{(3)} t^2 u^2 \\ z_\mu^{(3)} t u^2 & \hat{y}_\mu t u + z_\mu^{(1)} t u^2 & z_\mu^{(2)} t u^2 \\ z_\tau^{(2)} u^2 & z_\tau^{(3)} u^2 & \hat{y}_\tau u + z_\tau^{(1)} u^2 \end{pmatrix} \quad (38)$$

with

$$\begin{aligned} z_f^{(1)} &= y_f c_1 + y'_f c_1^* e^{-4i\psi} + y_f^2 + y_f^3 e^{-4i\psi} + y_f^4 e^{-2i\psi} + y_f^6 c_a^* c_b e^{-2i\psi} + y_f^7 c_a c_b^* e^{-2i\psi} , \\ z_f^{(2)} &= y_f c_3 + y'_f c_2^* e^{-4i\psi} + y_f^6 c_a^* c_b e^{-2i\psi} + y_f^7 c_a c_b^* e^{-2i\psi} , \\ z_f^{(3)} &= y_f c_2 + y'_f c_3^* e^{-4i\psi} + y_f^6 c_a^* c_b e^{-2i\psi} + y_f^7 c_a c_b^* e^{-2i\psi} \end{aligned}$$

for $f = e, \mu, \tau$. We indicate complex conjugation via $*$ and recognize that for $u = |u| e^{i\psi}$ u^* reads $u e^{-2i\psi}$. Note that the off-diagonal elements of y_l , proportional to $z_f^{(2,3)}$, originate either from the sub-leading contributions to the VEV of the φ_T multiplet (coefficients $c_{2,3}$), or from a double flavon insertion of the type $\xi^\dagger \varphi_S$ or $\xi \varphi_S^\dagger$ (coefficients $c_{a,b}$). Note further that in the case $c_2 = c_3$ $z_f^{(2)}$ also equals $z_f^{(3)}$.

Similarly, the Lagrangian giving rise to neutrino masses can be expanded as:

$$\mathcal{L}_\nu = \mathcal{L}_\nu^{(1)} + \mathcal{L}_\nu^{(2)} + \dots \quad (39)$$

with the leading order terms:

$$\mathcal{L}_\nu^{(1)} = \frac{x_a}{\Lambda_f \Lambda_L} \xi (\tilde{H}^\dagger l \tilde{H}^\dagger l) + \frac{x_b}{\Lambda_f \Lambda_L} (\varphi_S \tilde{H}^\dagger l \tilde{H}^\dagger l) . \quad (40)$$

Due to the non-vanishing Z_3 charge of ξ and φ_S the terms equivalent to those in eq. (40) with $\xi^\dagger$ and $\varphi_S^\dagger$ are not invariant. $\mathcal{L}_\nu^{(1)}$ leads to eq. (14) with $a = x_a c_a$ and $b = x_b c_b$. $\mathcal{L}_\nu^{(2)}$ is not relevant for our discussion here, however gives rise to deviations of relative order $|u|$ from TB mixing.

4.3 Dipole moments

Coming to the last term of eq. (19), the one contributing to the dipole moments, we observe that $\mathcal{L}_{dip}$ and $\mathcal{L}_l$ have the same structure in flavour space and they only differ by the insertion of the electromagnetic field strength $\sigma \cdot F \equiv \sigma^{\mu\nu} F_{\mu\nu}$:

$$\mathcal{L}_{dip} = \mathcal{L}_{dip}^{(1)} + \mathcal{L}_{dip}^{(2)} + \dots \quad (41)$$

with

$$\begin{aligned} \mathcal{L}_{dip}^{(1)} &= i \frac{e}{M^2} \left[\frac{\beta_e}{\Lambda_f^3} \theta^2 e^c H^\dagger \sigma \cdot F (\varphi_T l) + \frac{\beta_\mu}{\Lambda_f^2} \theta \mu^c H^\dagger \sigma \cdot F (\varphi_T l)' + \frac{\beta_\tau}{\Lambda_f} \tau^c H^\dagger \sigma \cdot F (\varphi_T l)'' \right. \\ &\quad \left. + \frac{\beta'_e}{\Lambda_f^3} \theta^2 e^c H^\dagger \sigma \cdot F (\varphi_T^\dagger l) + \frac{\beta'_\mu}{\Lambda_f^2} \theta \mu^c H^\dagger \sigma \cdot F (\varphi_T^\dagger l)' + \frac{\beta'_\tau}{\Lambda_f} \tau^c H^\dagger \sigma \cdot F (\varphi_T^\dagger l)'' \right] + h.c. \end{aligned} \quad (42)$$

and

$$\mathcal{L}_{dip}^{(2)} = i \frac{e}{M^2} \sum_{i=2}^7 \left[\frac{\beta_e^i}{\Lambda_f^4} \theta^2 e^c H^\dagger \sigma \cdot F(X_i l) + \frac{\beta_\mu^i}{\Lambda_f^3} \theta \mu^c H^\dagger \sigma \cdot F(X_i l)' + \frac{\beta_\tau^i}{\Lambda_f^2} \tau^c H^\dagger \sigma \cdot F(X_i l)'' \right] + h.c. \quad (43)$$

Since the Yukawa and the dipole couplings involve the same fermion fields and flavons, all statements made concerning eqs. (35) and (37) also hold for eqs. (42) and (43). From eqs. (42) and (43), after the breaking of the flavour and electroweak symmetries, we find the following matrix for the dipole moments:

$$\mathcal{M} = \begin{pmatrix} \hat{\beta}_e t^2 u + \gamma_e^{(1)} t^2 u^2 & \gamma_e^{(2)} t^2 u^2 & \gamma_e^{(3)} t^2 u^2 \\ \gamma_\mu^{(3)} t u^2 & \hat{\beta}_\mu t u + \gamma_\mu^{(1)} t u^2 & \gamma_\mu^{(2)} t u^2 \\ \gamma_\tau^{(2)} u^2 & \gamma_\tau^{(3)} u^2 & \hat{\beta}_\tau u + \gamma_\tau^{(1)} u^2 \end{pmatrix} \quad (44)$$

with

$$\begin{aligned} \hat{\beta}_f &= \beta_f + \beta'_f e^{-2i\psi} , \\ \gamma_f^{(1)} &= \beta_f c_1 + \beta'_f c_1^* e^{-4i\psi} + \beta_f^2 + \beta_f^3 e^{-4i\psi} + \beta_f^4 e^{-2i\psi} + \beta_f^6 c_a^* c_b e^{-2i\psi} + \beta_f^7 c_a c_b^* e^{-2i\psi} , \\ \gamma_f^{(2)} &= \beta_f c_3 + \beta'_f c_2^* e^{-4i\psi} + \beta_f^6 c_a^* c_b e^{-2i\psi} + \beta_f^7 c_a c_b^* e^{-2i\psi} , \\ \gamma_f^{(3)} &= \beta_f c_2 + \beta'_f c_3^* e^{-4i\psi} + \beta_f^6 c_a^* c_b e^{-2i\psi} + \beta_f^7 c_a c_b^* e^{-2i\psi} \end{aligned} \quad (45)$$

for $f = e, \mu, \tau$. We observe that, in analogy to what occurs in y_l , the off-diagonal elements of $\mathcal{M}$, proportional to $\gamma_f^{(2,3)}$, originate either from the sub-leading contributions to the VEV of the φ_T multiplet (coefficients $c_{2,3}$), or from a double flavon insertion of the type $\xi^\dagger \varphi_S$ or $\xi \varphi_S^\dagger$ (coefficients $c_{a,b}$). For $c_2 = c_3$ $\gamma_f^{(2)}$ and $\gamma_f^{(3)}$ become equal. This is similar to $z_f^{(2)} = z_f^{(3)}$ in the case of y_l .

4.4 Four-fermion operators

A complete classification of $SU(2) \times U(1)$, Lorentz and G_f invariant four-lepton operators goes beyond the scope of this work and here we limit ourselves to some remarks. At variance with the operators controlled by the matrix $\mathcal{M}$, that vanish when either the Higgs doublet or the flavon fields are set to zero, four-fermion operators exist that do neither require the insertion of the Higgs field, nor the insertion of a flavon field [17, 21, 23, 29]. A first group of terms includes

$$\frac{1}{M^2} \overline{f^c} f^c \overline{f'^c} f'^c , \quad \frac{1}{M^2} \overline{f^c} f^c (\bar{l}l) \quad (f, f' = e, \mu, \tau) . \quad (46)$$

These operators conserve the individual lepton numbers. When they contain electrons they are bound by LEP II data, that typically require a scale M above several TeV. A second group consists of:

$$\frac{1}{M^2} \overline{e^c} \mu^c \overline{\tau^c} \mu^c , \quad \frac{1}{M^2} (\bar{l}l \bar{l}l) \quad (47)$$

and their conjugates. The second combination in eq. (47) stands for several independent invariants, obtained through different contractions of the involved A_4 triplets. This other

set gives rise to interactions that violate the individual lepton numbers L_i , with the selection rule $\Delta L_e \Delta L_\mu \Delta L_\tau = \pm 2$. For instance, one such interaction is given by

$$(\bar{l}l)'(\bar{l}l)'' = \bar{l}_e l_e \bar{l}_\mu l_\mu + \bar{l}_\mu l_\mu \bar{l}_\tau l_\tau + \bar{l}_\tau l_\tau \bar{l}_e l_e + [\bar{l}_e l_\tau \bar{l}_\mu l_\tau + \bar{l}_\mu l_e \bar{l}_\tau l_e + \bar{l}_\tau l_\mu \bar{l}_e l_\mu + h.c.] \quad . \quad (48)$$

These operators can contribute to LFV decays like $\tau^- \rightarrow \mu^+ e^- e^-$, $\tau^- \rightarrow e^+ \mu^- \mu^-$ and their conjugate, whose branching ratios have upper bounds of the order of 10^{-7} [30]. By assuming that these operators enter the low-energy Lagrangian with generic order one coefficients, through a rough dimensional estimate we find

$$\frac{1}{G_F^2 M^4} < 10^{-7} \quad (49)$$

and we get a lower bound on the scale M of the order of 15 TeV. A more detailed analysis of these operators and of the associated phenomenology will be presented elsewhere.

5 Dipole transitions

The physical observable quantities we are interested in, MDMs, EDMs and flavour violating transitions for leptons, can be computed from the effective Lagrangian of eq. (4), whose terms have been detailed in the previous section. If we work at the lowest order in the symmetry breaking parameter u , the kinetic terms are canonical (zeroth order in u) and y_l is diagonal (first order in u). In this approximation also the dipole matrix $\mathcal{M}$ is diagonal and it only contributes to lepton MDMs and EDMs, which we will discuss below. In order to find also the size of the flavour violating processes we need to include the sub-leading effects originating from insertions of the flavon fields $\varphi_{S,T}$ and ξ , shifts of the VEV of φ_T and (additional) insertions of θ in the Lagrangian. As shown above, these generate non-canonically normalized K and K^c , eq. (31) and eq. (32), and render y_l and $\mathcal{M}$ non-diagonal, eq. (38) and eq. (44). Therefore, we first have to move to the basis where the kinetic terms are canonically normalized and the charged lepton mass matrix is diagonal. After performing the necessary steps which are outlined in appendix B, we arrive at the following leading order result for the dipole matrix that, in this basis, will be denoted by $\hat{\mathcal{M}}$:

$$\begin{aligned} \hat{\mathcal{M}}_{ee} &= \hat{\beta}_e t^2 u \quad , \\ \hat{\mathcal{M}}_{e\mu} &= \frac{1}{\hat{y}_\mu^2} (z_\mu^{(3)} \hat{y}_\mu \hat{\beta}_e + \hat{y}_\mu^2 \gamma_e^{(2)} - \hat{y}_e z_\mu^{(3)} \hat{\beta}_\mu - z_e^{(2)} \hat{y}_\mu \hat{\beta}_\mu) t^2 u^2 \quad , \\ \hat{\mathcal{M}}_{e\tau} &= \frac{1}{\hat{y}_\tau^2} (z_\tau^{(2)} \hat{y}_\tau \hat{\beta}_e + \hat{y}_\tau^2 \gamma_e^{(3)} - \hat{y}_e z_\tau^{(2)} \hat{\beta}_\tau - z_e^{(3)} \hat{y}_\tau \hat{\beta}_\tau) t^2 u^2 \quad , \\ \hat{\mathcal{M}}_{\mu e} &= \frac{1}{\hat{y}_\mu} (\hat{y}_\mu \gamma_\mu^{(3)} - z_\mu^{(3)} \hat{\beta}_\mu) t u^2 \quad , \\ \hat{\mathcal{M}}_{\mu\mu} &= \hat{\beta}_\mu t u \quad , \\ \hat{\mathcal{M}}_{\mu\tau} &= \frac{1}{\hat{y}_\tau^2} (\hat{y}_\tau z_\tau^{(3)} \hat{\beta}_\mu + \hat{y}_\tau^2 \gamma_\mu^{(2)} - z_\tau^{(3)} \hat{y}_\mu \hat{\beta}_\tau - z_\mu^{(2)} \hat{y}_\tau \hat{\beta}_\tau) t u^2 \quad , \\ \hat{\mathcal{M}}_{\tau e} &= \frac{1}{\hat{y}_\tau} (\hat{y}_\tau \gamma_\tau^{(2)} - z_\tau^{(2)} \hat{\beta}_\tau) u^2 \quad , \end{aligned} \quad (50)$$

$$\begin{aligned}\hat{\mathcal{M}}_{\tau\mu} &= \frac{1}{\hat{y}_\tau} (\hat{y}_\tau \gamma_\tau^{(3)} - z_\tau^{(3)} \hat{\beta}_\tau) u^2 \quad , \\ \hat{\mathcal{M}}_{\tau\tau} &= \hat{\beta}_\tau u \quad .\end{aligned}$$

The results shown here have been obtained under the assumption that all parameters are real, as explained in appendix B, but they remain unchanged in the complex case as far as the diagonal elements of $\hat{\mathcal{M}}$ are concerned. Notice that, in general, all entries of $\hat{\mathcal{M}}$, after applying the appropriate transformations for canonical normalization of the kinetic terms and diagonalization of the charged lepton mass matrix, are of the same order as the corresponding entries of $\mathcal{M}$ before the transformations, see eq. (44). This is expected, if no additional cancellation or enhancement takes place. Note further that the structure of the leading order result is surprisingly simple, since it does not involve parameters appearing in the non-canonically normalized kinetic terms. By having a closer look at the explicit form of $\hat{\mathcal{M}}_{ij}$ one sees that the elements above the diagonal of $\hat{\mathcal{M}}$, $\hat{\mathcal{M}}_{e\mu}$, $\hat{\mathcal{M}}_{e\tau}$ and $\hat{\mathcal{M}}_{\mu\tau}$, have a similar structure. Similarly, the elements $\hat{\mathcal{M}}_{ij}$ below the diagonal, $\hat{\mathcal{M}}_{\mu e}$, $\hat{\mathcal{M}}_{\tau e}$ and $\hat{\mathcal{M}}_{\tau\mu}$, have a common structure. Finally, note that for $c_2 = c_3$, which implies $z_f^{(2)} = z_f^{(3)}$ and $\gamma_f^{(2)} = \gamma_f^{(3)}$, the elements $\hat{\mathcal{M}}_{\tau e}$ and $\hat{\mathcal{M}}_{\tau\mu}$ become equal. The MDMs and EDMs are given at lowest order as:

$$\begin{aligned}a_e &= 2m_e \frac{v}{\sqrt{2}M^2} \text{Re}(\hat{\beta}_e t^2 u) \quad , \\ a_\mu &= 2m_\mu \frac{v}{\sqrt{2}M^2} \text{Re}(\hat{\beta}_\mu t u) \quad , \\ a_\tau &= 2m_\tau \frac{v}{\sqrt{2}M^2} \text{Re}(\hat{\beta}_\tau u) \quad ,\end{aligned}\tag{51}$$

and

$$\begin{aligned}d_e &= e \frac{v}{\sqrt{2}M^2} \text{Im}(\hat{\beta}_e t^2 u) \quad , \\ d_\mu &= e \frac{v}{\sqrt{2}M^2} \text{Im}(\hat{\beta}_\mu t u) \quad , \\ d_\tau &= e \frac{v}{\sqrt{2}M^2} \text{Im}(\hat{\beta}_\tau u) \quad .\end{aligned}\tag{52}$$

As we have anticipated, MDMs and EDMs arise at first order in the u parameter. As a consequence their expressions in eqs. (51) and (52) depend neither on the parameters $\hat{y}_f$ and $z_f^{(k)}$ of the charged lepton mass matrix, nor on the off-diagonal elements of $\mathcal{M}$, but only on $\hat{\beta}_f$, at the leading order. Notice that, for coefficients $\hat{\beta}_f$ with absolute values and phases of order one, as expected in our model, we have:

$$a_i = O\left(2 \frac{m_i^2}{M^2}\right) \quad , \quad d_i = O\left(e \frac{m_i}{M^2}\right)\tag{53}$$

We can derive a bound on the scale M , by considering the existing limits on MDMs and EDMs and by using eqs. (53) as exact equalities to fix the ambiguity of the unknown coefficients $\hat{\beta}_f$. We find the results shown in table 2.

We see from table 2 that, in order to accept values of M in the range $1 \div 10$ TeV, we should invoke a cancellation in the imaginary part of $\hat{\mathcal{M}}_{ee}$, which can be either accidental

$d_e < 1.6 \times 10^{-27} \text{ e cm}$	$M > 80 \text{ TeV}$
$d_\mu < 2.8 \times 10^{-19} \text{ e cm}$	$M > 80 \text{ GeV}$
$\delta a_e < 3.8 \times 10^{-12}$	$M > 350 \text{ GeV}$
$\delta a_\mu \approx 30 \times 10^{-10}$	$M \approx 2.7 \text{ TeV}$

Table 2: Experimental limits on lepton MDMs and EDMs [30–32] and corresponding bounds on the scale M , derived from eqs. (53). The data on the τ lepton have not been reported since they are much less constraining. For the anomalous magnetic moment of the muon, δa_μ stands for the deviation of the experimental central value from the SM expectation.

or due to CP-conservation in the considered sector of the theory. Concerning the flavour violating dipole transitions, using eq. (50) we see that the rate for $l_i \rightarrow l_j \gamma$ is dominated by the contribution $\hat{\mathcal{M}}_{ij}$, since $\hat{\mathcal{M}}_{ji}$ is suppressed by a relative factor of $O(t)$ for $\mu \rightarrow e \gamma$ and $\tau \rightarrow \mu \gamma$ and of $O(t^2)$ for $\tau \rightarrow e \gamma$. We get:

$$\frac{BR(l_i \rightarrow l_j \gamma)}{BR(l_i \rightarrow l_j \nu_i \bar{\nu}_j)} = \frac{48\pi^3 \alpha}{G_F^2 M^4} |w_{ij} u|^2 \quad (54)$$

where

$$\begin{aligned} w_{\mu e} &= \frac{1}{\hat{y}_\mu^2} \left(\hat{y}_\mu \gamma_\mu^{(3)} - z_\mu^{(3)} \hat{\beta}_\mu \right) \\ w_{\tau \mu} &= \frac{1}{\hat{y}_\tau^2} \left(\hat{y}_\tau \gamma_\tau^{(3)} - z_\tau^{(3)} \hat{\beta}_\tau \right) \\ w_{\tau e} &= \frac{1}{\hat{y}_\tau^2} \left(\hat{y}_\tau \gamma_\tau^{(2)} - z_\tau^{(2)} \hat{\beta}_\tau \right) \quad . \end{aligned} \quad (55)$$

The form of w_{ij} shows that for each transition there are two contributions to the rate: one, proportional to $\gamma_i^{(2,3)}$, coming from the off-diagonal element (ij) of the original dipole matrix $\mathcal{M}$ and one, proportional to $z_i^{(2,3)}$, coming from the effect of diagonalizing the charged lepton mass matrix, see eqs. (44) and (38), respectively. Both contribute at the same order in u . Since the quantities w_{ij} are all expected to be of order one, we can conclude that in the class of models considered here the branching ratios for the three transitions $\mu \rightarrow e \gamma$, $\tau \rightarrow \mu \gamma$ and $\tau \rightarrow e \gamma$ should all be of the same order:

$$BR(\mu \rightarrow e \gamma) \approx BR(\tau \rightarrow \mu \gamma) \approx BR(\tau \rightarrow e \gamma) \quad . \quad (56)$$

This is a distinctive feature of our class of models, since in most of the other existing models there is a substantial difference between the branching ratios [11, 12, 33, 34]. In particular it often occurs that $BR(\mu \rightarrow e \gamma) < BR(\tau \rightarrow \mu \gamma)$. Given the present experimental bound $BR(\mu \rightarrow e \gamma) < 1.2 \times 10^{-11}$ [35], our result implies that $\tau \rightarrow \mu \gamma$ and $\tau \rightarrow e \gamma$ have rates much below the present and expected future sensitivity [36]. Moreover, from the current (future) experimental limit on $BR(\mu \rightarrow e \gamma)$ [35] and assuming $|w_{\mu e}| = 1$, we derive the following bound on $|u/M^2|$:

$$BR(\mu \rightarrow e \gamma) < 1.2 \times 10^{-11} \text{ (} 10^{-13} \text{)} \quad \left| \frac{u}{M^2} \right| < 1.2 \times 10^{-11} \text{ (} 1.1 \times 10^{-12} \text{)} \text{ GeV}^{-2} \quad . \quad (57)$$

Since the parameter $|u|$ lies in the limited range $0.001 < |u| < 0.05$, see eq. (18), we find

$$|u| = 0.001 \quad M > 10 \text{ (30) TeV} \quad (58)$$

$$|u| = 0.05 \quad M > 70 \text{ (200) TeV} \quad (59)$$

This pushes the scale M considerably above the range we were initially interested in. In particular M is shifted above the region of interest for $(g-2)_\mu$ and probably for LHC.

Since $\hat{\mathcal{M}}_{\tau e}$ and $\hat{\mathcal{M}}_{\tau\mu}$ become equal for $c_2 = c_3$, as explained above, also $w_{\tau e}$ and $w_{\tau\mu}$ in eq. (55) become equal and therefore also the branching ratio of $\tau \rightarrow e\gamma$ and $\tau \rightarrow \mu\gamma$ will be the same, at the leading order.

6 Supersymmetric case

As we have seen, the off-diagonal elements of the dipole matrix $\mathcal{M}$ can be traced back to two independent sources. They can originate either from $\mathcal{L}_{dip}^{(1)}$, when the sub-leading corrections to the VEV of the φ_T multiplet (terms proportional to $c_{1,2,3}$ in eq. (12)) are accounted for or from $\mathcal{L}_{dip}^{(2)}$, where the relevant double flavon insertions (see eq. (26)) are considered. In this second case, the only combinations of flavon insertions that can provide a non-vanishing contribution are $\xi^\dagger \varphi_S$ and its conjugate. In a generic case we expect that both these contributions are equally important and contribute at the same order to a given off-diagonal dipole transition. There is however a special case where the double flavon insertions $\xi^\dagger \varphi_S$ and its conjugate are suppressed compared to the sub-leading corrections to φ_T and an overall depletion in the elements of the matrix $\hat{\mathcal{M}}$ below the diagonal takes place. This happens, under certain conditions that we are going to specify, when the underlying theory is supersymmetric and supersymmetry is softly broken.

In order to understand the reason why in the supersymmetric case the insertions $\xi^\dagger \varphi_S$ and its conjugate are suppressed, it is useful to recall what are the expected sources of chirality flip in the lepton sector. In the supersymmetric case we have two Higgs doublets, $H_{u,d}$, and the field $H^\dagger$ of section 2 is replaced by H_d . Moreover, in the limit of unbroken supersymmetry the lepton mass terms are derived from the superpotential, which is holomorphic in the chiral superfields. At the leading order in the flavour symmetry breaking parameters, these terms are of the type:

$$\frac{1}{\Lambda_f} \int d^2\theta_{SUSY} \tau^c H_d (\varphi_T l)'' \quad (60)$$

and similarly for the other charged fermions. Therefore the terms in $\mathcal{L}_l^{(1,2)}$ containing non-holomorphic fields like $\varphi_T^\dagger$ and X_i ($i = 3, \dots, 7$) vanish in the supersymmetric limit:

$$y'_f = 0 \quad , \quad y_f^k = 0 \quad (k = 3, \dots, 7) \quad (61)$$

As a matter of fact, in a realistic model supersymmetry is broken, for instance by the VEV F of the θ_{SUSY}^2 component of a chiral superfield. Here we assume that supersymmetry breaking originates in a hidden sector of the theory and is transmitted to the observable sector via interactions suppressed by the scale Λ_f or by a larger scale, giving rise to soft

supersymmetry breaking terms with a typical mass scale of order m_{SUSY} . Supersymmetry breaking can give rise to non-holomorphic contributions to lepton masses, which are however suppressed by powers of m_{SUSY}/Λ_f , as in the following example:

$$\frac{1}{\Lambda_f^2} \int d^2\theta_{SUSY} d^2\bar{\theta}_{SUSY} \tau^c H_d(\varphi_T^\dagger l)'' \bar{\theta}_{SUSY}^2 m_{SUSY} \quad (62)$$

The ratio m_{SUSY}/Λ_f is a tiny quantity, which we will neglect in our analysis.

Beyond fermion mass terms another source of chirality flip is provided by the slepton mass terms of left-right type, which involve both an $SU(2)$ doublet and an $SU(2)$ singlet slepton. At the leading order in the supersymmetry breaking parameter m_{SUSY} , such soft breaking masses do not contain any insertion of anti-holomorphic fields like $\varphi_{T,S}^\dagger$ and $\xi^\dagger$. Indeed insertions of holomorphic supermultiplets only require one power of m_{SUSY} as in the following example

$$\frac{1}{\Lambda_f} \int d^2\theta_{SUSY} \tau^c H_d(\varphi_T l)'' \theta_{SUSY}^2 m_{SUSY} \quad . \quad (63)$$

On the contrary the insertion of an anti-holomorphic supermultiplet requires two powers of m_{SUSY} :

$$\frac{1}{\Lambda_f^2} \int d^2\theta_{SUSY} d^2\bar{\theta}_{SUSY} \tau^c H_d(\varphi_T^\dagger l)'' \theta_{SUSY}^2 \bar{\theta}_{SUSY}^2 m_{SUSY}^2 \quad . \quad (64)$$

In our approximation we will also neglect all contributions of the type in eq. (64). Furthermore, we assume that in the underlying fundamental theory the only sources of chirality flip are either fermion masses or sfermion masses of left-right type. Both of them, up to the order u^2 , are described by the insertion of φ_T or φ_T^2 in the relevant operators. This is our definition of the "supersymmetric case". Therefore in the supersymmetric case we should use the restrictions shown in eqs. (61). The fact that any chirality flip up to the order u^2 necessarily requires the insertion of φ_T or φ_T^2 also applies to the operators of $\mathcal{L}_{dip}$, and we have (analogously to eq. (61)):

$$\beta'_f = 0 \quad , \quad \beta_f^k = 0 \quad (k = 3, \dots, 7) \quad . \quad (65)$$

By applying eqs. (61) and (65) we find the following matrices y_l and $\mathcal{M}$ in the supersymmetric case:

$$y_l = \begin{pmatrix} y_e t^2 u + (y_e c_1 + y_e^2) t^2 u^2 & y_e c_3 t^2 u^2 & y_e c_2 t^2 u^2 \\ y_\mu c_2 t u^2 & y_\mu t u + (y_\mu c_1 + y_\mu^2) t u^2 & y_\mu c_3 t u^2 \\ y_\tau c_3 u^2 & y_\tau c_2 u^2 & y_\tau u + (y_\tau c_1 + y_\tau^2) u^2 \end{pmatrix} \quad (66)$$

and

$$\mathcal{M} = \begin{pmatrix} \beta_e t^2 u + (\beta_e c_1 + \beta_e^2) t^2 u^2 & \beta_e c_3 t^2 u^2 & \beta_e c_2 t^2 u^2 \\ \beta_\mu c_2 t u^2 & \beta_\mu t u + (\beta_\mu c_1 + \beta_\mu^2) t u^2 & \beta_\mu c_3 t u^2 \\ \beta_\tau c_3 u^2 & \beta_\tau c_2 u^2 & \beta_\tau u + (\beta_\tau c_1 + \beta_\tau^2) u^2 \end{pmatrix} \quad (67)$$

The procedure to arrive at $\hat{\mathcal{M}}$ is exactly the same as before. Thereby, note that the form of the kinetic terms K and K^c is the same as before, since supersymmetry puts no restriction on these terms. The result for the entries of $\hat{\mathcal{M}}$ is then⁸:

$$\begin{aligned}
\hat{\mathcal{M}}_{ee} &= \beta_e t^2 u \quad , \\
\hat{\mathcal{M}}_{e\mu} &= \frac{c_2 + c_3}{y_\mu} (\beta_e y_\mu - y_e \beta_\mu) t^2 u^2 \quad , \\
\hat{\mathcal{M}}_{e\tau} &= \frac{c_2 + c_3}{y_\tau} (\beta_e y_\tau - y_e \beta_\tau) t^2 u^2 \quad , \\
\hat{\mathcal{M}}_{\mu e} &= \frac{c_2}{y_\mu} (y_\mu^2 \beta_\mu - \beta_\mu^2 y_\mu) t u^3 \quad , \\
\hat{\mathcal{M}}_{\mu\mu} &= \beta_\mu t u \quad , \\
\hat{\mathcal{M}}_{\mu\tau} &= \frac{c_2 + c_3}{y_\tau} (\beta_\mu y_\tau - \beta_\tau y_\mu) t u^2 \quad , \\
\hat{\mathcal{M}}_{\tau e} &= \frac{c_3}{y_\tau} (y_\tau^2 \beta_\tau - \beta_\tau^2 y_\tau) u^3 \quad , \\
\hat{\mathcal{M}}_{\tau\mu} &= \frac{c_2}{y_\tau} (y_\tau^2 \beta_\tau - \beta_\tau^2 y_\tau) u^3 \quad , \\
\hat{\mathcal{M}}_{\tau\tau} &= \beta_\tau u \quad .
\end{aligned} \tag{68}$$

Again, the leading order results are not affected by the non-canonically normalized kinetic terms and therefore are rather simple. Also here, the elements above the diagonal $\hat{\mathcal{M}}_{ij}$ have a common structure, i.e. they are determined by the sum of c_2 and c_3 and the parameters y_f and $\beta_{f'}$ where indices f and f' are determined by i as well as j . Similarly, for the elements $\hat{\mathcal{M}}_{ij}$ below the diagonal we find that they are either proportional to c_2 or c_3 and the index f of all parameters is solely given by the index i of $\hat{\mathcal{M}}_{ij}$. In this case the equality of $\hat{\mathcal{M}}_{\tau e}$ and $\hat{\mathcal{M}}_{\tau\mu}$ for $c_2 = c_3$ also holds and is more obvious than in the general case. The EDMs and MDMs are similar to those of the general non-supersymmetric case: we find the same degree of suppression in the t and u parameters for the physical quantities. The difference between the general and the supersymmetric approaches becomes manifest when the sub-leading corrections are taken into account, i.e. only in the study of the LFV processes. The main difference is the suppression of the elements below the diagonal which are not of the order as expected from eq. (67), but suppressed by an additional power of u . We get

$$\frac{BR(l_i \rightarrow l_j \gamma)}{BR(l_i \rightarrow l_j \nu_i \bar{\nu}_j)} = \frac{48\pi^3 \alpha}{G_F^2 M^4} \left[|w_{ij}^{(1)} u^2|^2 + \frac{m_j^2}{m_i^2} |w_{ij}^{(2)} u|^2 \right] \tag{69}$$

where

$$w_{\mu e}^{(1)} = \frac{c_2}{y_\mu^2} (y_\mu^2 \beta_\mu - \beta_\mu^2 y_\mu) \quad w_{\mu e}^{(2)} = \frac{c_2 + c_3}{y_\mu y_e} (\beta_e y_\mu - y_e \beta_\mu) \tag{70}$$

$$w_{\tau\mu}^{(1)} = \frac{c_2}{y_\tau^2} (y_\tau^2 \beta_\tau - \beta_\tau^2 y_\tau) \quad w_{\tau\mu}^{(2)} = \frac{c_2 + c_3}{y_\tau y_\mu} (\beta_\mu y_\tau - \beta_\tau y_\mu) \tag{71}$$

$$w_{\tau e}^{(1)} = \frac{c_3}{y_\tau^2} (y_\tau^2 \beta_\tau - \beta_\tau^2 y_\tau) \quad w_{\tau e}^{(2)} = \frac{c_2 + c_3}{y_\tau y_e} (\beta_e y_\tau - y_e \beta_\tau) \tag{72}$$

⁸Note that if we take the formulae given in eqs. (50) and use eqs. (61) and (65) we also arrive at this form of $\hat{\mathcal{M}}_{ij}$. Thereby, the elements $\hat{\mathcal{M}}_{\mu e}$, $\hat{\mathcal{M}}_{\tau e}$ and $\hat{\mathcal{M}}_{\tau\mu}$ below the diagonal turn out to be zero, i.e. we can also deduce the suppression of these elements, however not their exact form.

Figure 1: The branching ratio of $\mu \rightarrow e\gamma$ as a function of $|u|$, eq. (75). The deviation of the anomalous magnetic moment of the muon from the SM expectation is kept fixed to its experimental range [32]. The unknown coefficients $\tilde{w}_{\mu e}^{(1,2)}$ are equal to 1 (darker region) or are random complex numbers with absolute values between zero and two (lighter region). The continuous (dashed) horizontal line corresponds to the present (future expected) experimental bound on $BR(\mu \rightarrow e\gamma)$ [35].

Notice that now the first contribution on the right-hand side of eq. (69) is suppressed by a factor of u compared to the non-supersymmetric case. In most of the allowed range of u , the branching ratios of $\mu \rightarrow e\gamma$ and $\tau \rightarrow \mu\gamma$ are similar and larger than the branching ratio of $\tau \rightarrow e\gamma$. Assuming $|w_{\mu e}^{(1,2)}| = 1$, the present (future) experimental limit on $BR(\mu \rightarrow e\gamma)$ implies the following bounds

$$|u| = 0.001 \quad M > 0.7 \text{ (2) TeV} \quad (73)$$

$$|u| = 0.05 \quad M > 14 \text{ (48) TeV} \quad . \quad (74)$$

We see that at variance with the non-supersymmetric case there is a range of permitted values of the parameter $|u|$ for which the scale M can be sufficiently small to allow an explanation of the observed discrepancy in a_μ , without conflicting with the present bound on $BR(\mu \rightarrow e\gamma)$. We can eliminate the dependence on the unknown scale M by combining eqs. (53) and (69). For $\mu \rightarrow e\gamma$ we get⁹:

$$\frac{BR(\mu \rightarrow e\gamma)}{BR(\mu \rightarrow e\nu_\mu\bar{\nu}_e)} = \frac{12\pi^3\alpha}{G_F^2 m_\mu^4} (\delta a_\mu)^2 \left[|\tilde{w}_{\mu e}^{(1)}|^2 |u|^4 + \frac{m_e^2}{m_\mu^2} |\tilde{w}_{\mu e}^{(2)}|^2 |u|^2 \right] \quad (75)$$

where $\tilde{w}_{\mu e}^{(1,2)}$ are unknown, order one coefficients. We plot $BR(\mu \rightarrow e\gamma)$ versus $|u|$ in fig. 1, where the coefficients $\tilde{w}_{\mu e}^{(1,2)}$ are kept fixed to 1 (darker region) or are random complex numbers with absolute values between zero and two (lighter region). The deviation of the anomalous magnetic moment of the muon from the SM prediction is in the interval of the

⁹Relations among $BR(\mu \rightarrow e\gamma)$, δa_μ and neutrino mass parameters have also been discussed in [37].

experimentally allowed values, about three sigma away from zero. Even if the ignorance about the coefficients $\tilde{w}_{\mu e}^{(1,2)}$ does not allow us to derive a sharp limit on $|u|$, we see that the present limit on $BR(\mu \rightarrow e\gamma)$ disfavors values of $|u|$ larger than few percents. We recall that in this model the magnitudes of $|u|$ and θ_{13} are comparable.

7 Comparison with Minimal Flavour Violation

It is instructive to compare the previous results with those of MFV [11, 12]. If we restrict ourselves to the case where right-handed neutrinos do not affect the flavour properties of the theory, the flavour group of MFV is $G_f = SU(3)_{e^c} \times SU(3)_l \times \dots$, where we have only displayed the part relevant for the lepton sector. Electroweak singlets e^c and doublets l transform as $(3, 1)$ and $(1, \bar{3})$, respectively. The flavon fields or, better, their VEVs are the Yukawa couplings y_l and Y themselves, transforming as $(\bar{3}, 3)$ and $(1, 6)$, respectively. By going to a basis where the charged leptons are diagonal, y_l and Y can be expressed in terms of lepton masses and mixing angles (we keep using a notation where a hat denotes matrices in this particular basis):

$$\hat{y}_l = \frac{\sqrt{2}}{v} m_l^{\text{diag}} \quad , \quad \hat{Y} = \frac{\Lambda_L}{v^2} U^* m_\nu^{\text{diag}} U^\dagger \quad , \quad (76)$$

where U is the lepton mixing matrix. The diagonal elements of the matrix $\hat{\mathcal{M}}$ evaluated in MFV are analogous to those of the previous class of models and similar bounds on the scale M are derived from the existing data on MDMs and EDMs. The off-diagonal elements are given by:

$$\begin{aligned} \hat{\mathcal{M}}_{ij} &= \beta (\hat{y}_l \hat{Y}^\dagger \hat{Y})_{ij} \\ &= \sqrt{2} \beta \frac{m_i}{v} \frac{\Lambda_L^2}{v^4} [\Delta m_{sol}^2 U_{i2} U_{j2}^* \pm \Delta m_{atm}^2 U_{i3} U_{j3}^*] \end{aligned} \quad (77)$$

where β is an overall coefficient of order one and the plus (minus) sign refers to the case of normal (inverted) hierarchy. We see that, due to the presence of the ratio Λ_L^2/v^2 the overall scale of these matrix elements is much less constrained than in the previous case. This is due to the fact that MFV does not restrict the overall strength of the coupling constants Y , apart from the requirement that they remain in the perturbative regime. Very small or relatively large (but smaller than one) Y can be accommodated by adjusting the scale Λ_L . On the contrary this is not allowed in the case previously discussed where the size of the symmetry breaking effects is restricted to the small window (18) and the scale Λ_L is determined within a factor of about fifty. The conclusion is that in MFV the non-observation of $l_i \rightarrow l_j \gamma$ could be justified by choosing a small Λ_L , while a positive signal in $\mu \rightarrow e \gamma$ with a branching ratio in the range $1.2 \times 10^{-11} \div 10^{-13}$ could also be fitted by an appropriate Λ_L , apart from a small region of the θ_{13} angle, around $\theta_{13} \approx 0.02$ where a cancellation can take place.

The dependence on the scale Λ_L is eliminated by considering ratios of branching ratios. For instance:

$$\frac{BR(\mu \rightarrow e \gamma)}{BR(\mu \rightarrow e \nu_\mu \bar{\nu}_e)} \frac{BR(\tau \rightarrow \mu \nu_\tau \bar{\nu}_\mu)}{BR(\tau \rightarrow \mu \gamma)} = \left| \frac{2\Delta m_{sol}^2}{3\Delta m_{atm}^2} \pm \sqrt{2} \sin \theta_{13} e^{i\delta} \right|^2 < 1 \quad , \quad (78)$$

where we took the TB ansatz, see eq. (1), to fix θ_{12} and θ_{23} . We see that $BR(\mu \rightarrow e\gamma) < BR(\tau \rightarrow \mu\gamma)$ always in MFV. Moreover, for θ_{13} above approximately 0.07, $BR(\mu \rightarrow e\gamma) < 1.2 \times 10^{-11}$ implies $BR(\tau \rightarrow \mu\gamma) < 10^{-9}$. For θ_{13} below 0.07, apart possibly from a small region around $\theta_{13} \approx 0.02$, both the transitions $\mu \rightarrow e\gamma$ and $\tau \rightarrow \mu\gamma$ might be above the sensitivity of the future experiments.

We also observe that in MFV the only difference between the general case and the supersymmetric one is the presence of two doublets in the low-energy Lagrangian. In MFV a chirality flip in leptonic operators necessarily requires the insertion of the matrix $\hat{y}_l$, both in the general and in the supersymmetric case and, apart from the possibility of $\tan\beta$ enhanced contributions, similar predictions for the LFV processes are expected in the two cases.

8 Conclusion

Flavour mixing within lepton families is surprisingly close to the TB one [3], with a striking agreement for the solar and the atmospheric mixing angles. The closeness of the lepton mixing to the TB one is still waiting for a full experimental confirmation, which could be provided by the evidence for a relatively small angle θ_{13} , of the order of few degrees. In the recent years several models of lepton masses and mixing angles predicting an approximate TB mixing have been proposed [5–10, 24]. A particularly simple model is the one based on the flavour symmetry $A_4 \times Z_3 \times U(1)_{FN}$ [6–8], which represents a sort of minimal choice to properly account for both, the neutrino and the charged lepton sector. The TB mixing originates from the misalignment of the scalar multiplets φ that break A_4 giving masses to neutrinos and to charged leptons. In this paper we have analyzed a set of new low-energy predictions of models invariant under the flavour symmetry $A_4 \times Z_3 \times U(1)_{FN}$. These predictions involve leptonic MDMs, EDMs and LFV transitions like $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$. We have constructed the effective low-energy Lagrangian that describes these observables. Such an effective Lagrangian is invariant under the flavour symmetry, and all flavour breaking effects are encoded in the dependence on the spurions $\Phi \equiv \varphi/\Lambda_f$ (Λ_f being the cut-off of the theory). These also control lepton masses and mixing angles. The dominant operators are obtained by expanding the Lagrangian in powers of Φ and by keeping the first few terms in the expansion. The leading contributions have dimension six and are suppressed by two powers of a new scale M . This scale can be considerably smaller than the other scales of the problem, like the cut-off Λ_f , the VEV of the flavons $\langle\varphi\rangle$ and the scale of lepton number violation Λ_L . We treat M as an independent parameter, to be constrained by the experiments. Apart from the scale M , all the relevant information needed to predict MDMs, EDMs and LFV transitions is contained in a dimensionless matrix $\hat{\mathcal{M}}$, whose elements can be computed up to unknown order-one coefficients from our Lagrangian. The strongest bound comes from the EDM of the electron [31] : $M > 80$ TeV. A lower value for M can be tolerated in the presence of a cancellation in the imaginary part of $\hat{\mathcal{M}}_{ee}$, perhaps related to CP-conservation in the considered sector of the theory. This problem is also present in MFV [11, 12], where one simply assumes that $\hat{\mathcal{M}}_{ee}$ is real. Another stringent bound can be derived from the analysis of the τ decays

$\tau^- \rightarrow \mu^+ e^- e^-$ and $\tau^- \rightarrow e^+ \mu^- \mu^-$ [30] that, barring cancellations in the coefficients of the relevant operators, push the scale M above approximately 15 TeV. Coming to LFV dipole transitions, we have found that in the general case the branching ratios for $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ are all expected to be of the same order, at variance with MFV. Given the present limit on $BR(\mu \rightarrow e\gamma)$ [35], this implies that $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ have rates much smaller than the present (and near future) sensitivity [36]. The absolute values of these branching ratios depend on the spurion VEVs $\langle\Phi\rangle$ that in our class of models are determined by a parameter $|u|$ in the range $0.001 < |u| < 0.05$. In the general case, for $BR(\mu \rightarrow e\gamma) < 1.2 \times 10^{-11}$ (10^{-13}) we get $M > 10$ (30) TeV if $|u| = 0.001$ and $M > 70$ (200) TeV for $|u| = 0.05$. The anomalous MDM of the muon a_μ and its deviation from the SM expectation [32] provide the indication for a lower scale M , of the order of few TeV, which would also be of great interest for LHC. In order to reconcile this possibility with the results derived from the LFV dipole transitions, we have reconsidered the matrix $\hat{\mathcal{M}}$ in a supersymmetric context, where additional constraints have to be applied. The operators describing $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ flip the lepton chirality. By assuming that in a supersymmetric theory the only sources of chirality flips are the fermion masses and the sfermion mass terms of left-right type, we find that a cancellation takes place in the elements of $\hat{\mathcal{M}}$ below the diagonal. As a result the limits on the scale M become less severe. For $BR(\mu \rightarrow e\gamma) < 1.2 \times 10^{-11}$ (10^{-13}) we get $M > 0.7$ (2) TeV if $|u| = 0.001$ and $M > 14$ (48) TeV for $|u| = 0.05$. At variance with the non-supersymmetric case there is a range of values of the parameter $|u|$ for which the scale M can be sufficiently small to allow for an explanation of the observed discrepancy in a_μ , without conflicting with the present bound on $\mu \rightarrow e\gamma$. Since in our framework θ_{13} is comparable to $|u|$, the present limit on $BR(\mu \rightarrow e\gamma)$ together with the existing discrepancy in a_μ point to a rather small value for θ_{13} , of the order of few percents in radians, close to but probably just below the sensitivity expected in future experiments at reactors or with high intensity neutrino beams [2, 38]. It remains to be seen if the bounds on the scale M derived from four-lepton operators can be evaded in the supersymmetric case.

Acknowledgments

We acknowledge useful discussions with Paolo Gambino, Michael A. Schmidt and with Fabio Zwirner. C.H. would like to thank the theory group of the University of Padua and the INFN section of Padua for very kind hospitality. We recognize that this work has been partly supported by the European Commission under contracts MRTN-CT-2004-503369 and MRTN-CT-2006-035505 and by the ‘‘Sonderforschungsbereich’’ TR27.

A The group A_4

The group A_4 is generated by two elements S and T obeying the relations [25]:

$$S^2 = (ST)^3 = T^3 = 1 \quad . \quad (79)$$

It has three independent one-dimensional representations, 1, $1'$ and $1''$ and one three-dimensional representation 3. The one-dimensional representations are given by:

$$\begin{aligned} 1 \quad S &= 1 \quad T = 1 \\ 1' \quad S &= 1 \quad T = e^{i4\pi/3} \equiv \omega^2 \\ 1'' \quad S &= 1 \quad T = e^{i2\pi/3} \equiv \omega \end{aligned} \quad (80)$$

The three-dimensional representation, in a basis where the generator T is diagonal, is given by:

$$T = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \omega^2 & 0 \\ 0 & 0 & \omega \end{pmatrix}, \quad S = \frac{1}{3} \begin{pmatrix} -1 & 2 & 2 \\ 2 & -1 & 2 \\ 2 & 2 & -1 \end{pmatrix} \quad . \quad (81)$$

The multiplication rule for triplet representations is the following:

$$3 \times 3 = 1 + 1' + 1'' + 3_S + 3_A \quad (82)$$

If we denote by

$$a = (a_1, a_2, a_3) \quad , \quad b = (b_1, b_2, b_3) \quad (83)$$

two triplets, the singlets contained in their product are given by

$$\begin{aligned} 1 &\equiv (ab) = (a_1b_1 + a_2b_3 + a_3b_2) \\ 1' &\equiv (ab)' = (a_3b_3 + a_1b_2 + a_2b_1) \\ 1'' &\equiv (ab)'' = (a_2b_2 + a_1b_3 + a_3b_1) \end{aligned} \quad (84)$$

The two triplets can be separated into a symmetric and an antisymmetric part:

$$\begin{aligned} 3_S \equiv (ab)_S &= \frac{1}{3}(2a_1b_1 - a_2b_3 - a_3b_2, 2a_3b_3 - a_1b_2 - a_2b_1, 2a_2b_2 - a_1b_3 - a_3b_1) \\ 3_A \equiv (ab)_A &= \frac{1}{2}(a_2b_3 - a_3b_2, a_1b_2 - a_2b_1, a_3b_1 - a_1b_3) \end{aligned} \quad (85)$$

Moreover, if c , c' and c'' are singlets transforming as 1, $1'$ and $1''$, and $a = (a_1, a_2, a_3)$ is a triplet, then the products ac , ac' and ac'' are triplets explicitly given by (a_1c, a_2c, a_3c) , (a_3c', a_1c', a_2c') and (a_2c'', a_3c'', a_1c'') , respectively. Note that due to the choice of complex representation matrices for the real representation 3 the conjugate a^* of $a \sim 3$ does not transform as 3, but rather (a_1^*, a_3^*, a_2^*) transforms as triplet under A_4 . The reason for this is that $T^* = U^T T U$ and $S^* = U^T S U = S$ where U is the matrix which exchanges the 2nd and 3rd row and column.

B Canonical Normalization of K and K^c & Diagonalization of y_l

We perform the following transformations on the fields present in the Lagrangian: at first K and K^c are brought into their canonical form and then y_l is diagonalized.

To diagonalize the hermitian matrices K and K^c we apply the unitary transformations W and W^c :

$$W^\dagger K W = \text{diag} \quad \text{and} \quad (W^c)^\dagger K^c W^c = \text{diag} . \quad (86)$$

Normalizing K and K^c requires a rescaling of the fields via the real (diagonal) matrices R and R^c :

$$R W^\dagger K W R = \mathbb{1} \quad \text{and} \quad R^c (W^c)^\dagger K^c W^c R^c = \mathbb{1} . \quad (87)$$

The fields l and e^c present in the original Lagrangian (here e^c stands for the three SU(2) singlet leptons) are expressed as:

$$l = W R l' \quad \text{and} \quad e^c = W^c R^c (e^c)' \quad (88)$$

so that $\bar{l} K l = \bar{l}' [R W^\dagger K W R] l' = \bar{l}' \mathbb{1} l'$ and $\bar{e}^c K^c e^c = (\bar{e}^c)' [R^c (W^c)^\dagger K^c W^c R^c] (e^c)' = (\bar{e}^c)' \mathbb{1} (e^c)'$ holds. y_l and $\mathcal{M}$ given in the basis l' and $(e^c)'$ take the form:

$$(e^c)^T y_l l = (e^c)'^T R^c (W^c)^T y_l W R l' , \quad (89)$$

and

$$(e^c)^T \mathcal{M} l = (e^c)'^T R^c (W^c)^T \mathcal{M} W R l' . \quad (90)$$

We diagonalize the resulting Yukawa couplings of the charged leptons, $R^c (W^c)^T y_l W R$, by the usual bi-unitary transformation:

$$U^T [R^c (W^c)^T y_l W R] V = \frac{\sqrt{2}}{v} \text{diag}(m_e, m_\mu, m_\tau) \quad (91)$$

and arrive at the mass eigenbasis l'' and $(e^c)''$:

$$(e^c)' = U (e^c)'' \quad \text{and} \quad l' = V l'' . \quad (92)$$

Finally, the matrix $\mathcal{M}$ for the dipole moments is given as:

$$(e^c)^T \mathcal{M} l = (e^c)''^T [U^T R^c (W^c)^T \mathcal{M} W R V] l'' \equiv (e^c)''^T \hat{\mathcal{M}} l'' . \quad (93)$$

Using $\hat{\mathcal{M}}$ we can immediately read off the size of MDMs, EDMs and LFV processes.

As we assume for the actual calculation of $\hat{\mathcal{M}}$ that all couplings involved are real, the matrices W , W^c , U and V turn out to be orthogonal instead of unitary. Furthermore, we express the small parameter u in terms of t as $u = xt$ with $|x| \leq 1$ according to eq. (15) and eq. (18). We then can do the calculation in just one expansion parameter t ¹⁰. In the course of the calculation we pose the following requirements: the kinetic terms are canonically normalized up to and including $O(t^5)$, y_l is diagonal also up to and including $O(t^5)$, and the matrices W , W^c , U and V are orthogonal up to the same order. The calculations have been performed with two independent methods.

¹⁰The different factors of t and u can be recovered in the final result by replacing x with $\frac{u}{t}$.
